

## Group projects Programming in Python II

**Deadline: 27/04/2022**, please submit your \*.py or \*.ipynb files using the designated folder on the K2 site of the course.

### **Project 1: Team 1 (Kenza Abdelhaq, Ismail Ben Achour, Charles Antoine Sol), Team 2 (Yuanfeng Rao), Team 13 (Mingxuan YANG, Kyungmin LEE)**

The task is to predict the logarithm of the hourly wages (in USD) (variable *lwage*) based on education (variable *educ*), work experience (variable *exper*), tenure (variable *tenure*) and gender (variable *female*). The gender is encoded in the variable *female* which is 1 for females, zero for males. The .csv file can be found at <https://www.kaggle.com/datasets/mihalypetreczky/wagedataset>.

Use various models (linear regression, SVM, decision tress, neural networks) for predicting the logarithm of wage. Compare the various models in terms of accuracy of prediction. Which one is the best ? Select one or two independent variables (say only the tenure and gender, or education and tenure, etc.) and use them to build models for predicting the logarithm of wage. Which variables are the most significant ones for predicting wage ? Repeat the exercise separately for males and females and for the wage instead of its logarithm.

### **Project 2: Team 3 (Morgane Baudin, Erwan Denoual, Valentin Sieuw), Team 4 (Bingjie GAO, Zeyue LIN, Zhiqi ZHENG)**

The task is to predict the logarithm of the house prices (variable *lprice*) using the following variables: logarithm of the lot size (variable *lplotsize*), logarithm of the surface of the house (variable *lsqft*), number of bedrooms (variable *bdrms*). The .csv file can be found at <https://www.kaggle.com/datasets/mihalypetreczky/hpric1>.

Use various models (linear regression, SVM, decision tress, neural networks) for predicting the logarithm house prices. Compare the various models in terms

of accuracy of prediction. Which one is the best ? Select one or two independent variables and use them to build models for predicting the logarithm of houses prices. Which variables are the most significant ones for predicting the logarithm of house prices ? Repeat the exercises with the house prices instead of their logarithm.

### **Project 3: Team 5 (Martin Vanpoperinghe, William Tollet, Maxime Bachelet) Team 6 (Ziqi ZHAO, Wanwen ZHAO, Thi Minh Huong PHAM)**

The task is to predict house prices in different communities based on air pollution level (represented by the concentration of nitrogine oxid), distance from employment centers, average student-teacher ratio in local schools and average number of rooms, and crime rate The variables are as follows:

- *price*  
median housing price
- *crime*  
crimes committed per capita
- *nox*  
nitrogine oxide, parts per 100 mill.
- *rooms*  
avg number of rooms per house
- *dist*  
weighted dist. to 5 employ centers
- *stratio*  
average student-teacher ratio
- *lprice*  
 $\log(\textit{price})$
- *lnox*  
 $\log(\textit{nox})$

The .csv file can be found at <https://www.kaggle.com/datasets/mihalytreczky/hprice2>.

Use various models (linear regression, SVM, decision tress, neural networks) for predicting house prices. Compare the various models in terms of accuracy of prediction. Which one is the best ? Select one or two independent variables and use them to build models for predicting houses prices. Which variables are the most significant ones for predicting house prices ? Try to predict the logarithm of house prices instead of house prices. Do you see any improvement in performance of the models ?

## Project 4: Team 7 (Emma GUEGUEN, Marie DE KONINCK, Eva ZARBO), Team 8 (Maximin Gnié Fokwa, Enzo Frare, Nicolas CARDINAL)

The task is to predict the price growth based on the monthly growth of the hourly wage. The variables are as follows

- *price*  
consumer price index
- *gwage*  
increase in hourly wage in the current month
- *gwage<sub>i</sub>*  
 $i = 1, \dots, 12$  increase in hourly wage in month = the current month -  $i$

The .csv file can be found at <https://www.kaggle.com/datasets/mihalytreczky/wageprcdataset>.

Use various models (linear regression, SVM, decision tress, neural networks) for predicting price growth. Compare the various models in terms of accuracy of prediction. Which one is the best ? Adapt the models to predict the price *price* based on *gwage*, *gwage<sub>1</sub>*, ..., *gwage<sub>n</sub>*, for  $n = 1, 2, \dots, 12$ . Which variables are the most significant ones for predicting prices ? Try to predict the logarithm of house prices instead of house prices. Do you see any improvement in performance of the models ?

## Project 5: Team 9 (Jeanne Terpraut, Thomas Certeux, Baptiste Guillou ) Team 10 (Elizaveta Larchenkova, Carmina Navarro, Kirane Yassine )

The task is to predict the inventory change based on GDP growth and on real interest rates. More precisely, the variables are as follows:

- *cinven*  
annual growth of inventory
- *cgdp*  
annual growth of GDP
- *r3*  
real interest rate
- *cr3*  
annual growth of the real interest rate
- *gdp*  
annual gdp

The .csv file can be found at <https://www.kaggle.com/datasets/mihalypetreczky/invendataset>.

Use various models (linear regression, SVM, decision tress, neural networks) for predicting inventory. Compare the various models in terms of accuracy of prediction. Which one is the best ? Select one or two independent variables and use them to build models for predicting inventory. Which variables are the most significant ones for predicting inventory ?

## **Project 6:Team 11( Emilie Coutaz, Julie Sansoucy, Mathieu Douziech), Team 12 (Vincent Braganti, Adrien Farges, Benjamin Groult)**

The task to predict logarithm of wages based on education, experience and IQ, hours worked. The variables are as follows:

- *lwage*  
logarithm monthly earnings
- *hours*  
average weekly hours
- *IQ*  
IQ score
- *educ*  
years of education
- *exper*  
years of work experience

The .csv file can be found at <https://www.kaggle.com/datasets/mihalypetreczky/wage2dataset>.

Use various models (linear regression, SVM, decision tress, neural networks) for predicting the logarithm of wage. Compare the various models in terms of accuracy of prediction. Which one is the best ? Select one or two independent variables and use them to build models for predicting the logarithm of wage. Which variables are the most significant ones for predicting the logarithm of wage ? Repeat the exercise for wage instead of its logarithm. Do you see any difference in the performance of various models ?
